

Homework: Frontend

You are developing a UI for a currency conversion service with configurable conversion fees.

Requirements

1. Create a form for editing a list of currency conversion fees.
 - Fees can be added, changed or removed for a given currency pair and direction.
 - Fees apply exactly in the configured direction. A conversion from EUR to GBP has its own fee that is different from a conversion from GBP to EUR (in the opposite direction).
 - Fees are specified as fractions. For example, `0.2` for a 20% fee.
 - Configured conversion fees are persisted to local storage.
2. Create a form for calculating a currency conversion.
 - The user enters the amount to be converted, the currency to convert from, and the currency to convert to.
 - The latest conversion rate should be fetched from either [BoL](#) or [ECB](#). Note that both endpoints respond with XML, not JSON.
 - A fee should be deducted from the initial amount before conversion. The fee is taken from the list of configured conversion fees.
 - If a fee is not configured, a default fee of `0.01` (i.e. 1%) is applied.
 - The conversion fee is subtracted from the amount before applying the currency rate: `(amount - amount * fee) * rate`.
 - It should be possible to convert from any supported currency to any other supported currency, not just from EUR. For example, it should be possible to convert from GBP to USD by deriving the conversion rate from their known EUR rates.

Non-functional Requirements

- Stack: TypeScript or JavaScript, React or Vue.
- The application should be built and served using a build tool of your choice (e.g. Create React App, Vite, or webpack). A production build is not required.
- The application should work entirely on the client side, including persistent data and network requests.
- The provided endpoints don't set CORS headers. In order to use them, you will have to configure a proxy. Your chosen build tool should support this feature.

Other Considerations

- It should be possible to test and run the application with terminal commands.
- You should provide a README file that explains how to do the above.
- We value robust and readable code, rather than visuals and extra features. Devote your time accordingly.
